

TP2

To avoid confusion between your work and others on the same machine, create a directory whose name is your full name and student number. Place the directory in www.

Use in this TP: \$_POST, fopen(), fwrite(), fgets(), fclose(), isset(), \$_SERVER['PHP_SELF']

The objective is to create a web site “**sarahah**” as follows:

At first, create a file “**index.php**”.

Then, create another file “**see.php**”

hello !

PHP TP2.

Try it !

The form in “**index.php**” should insert the message in a text file called messages.txt, where each line contains a message. The PHP code should be in the same file “index.php”. you can open the file messages.txt and add a new message manually.

The form in “**see.php**” should collect data with \$_POST and print all messages one by one. To read the messages, you should open the file messages.txt and read each line. You should have a form that contains Username/password to access the messages. And if you have an error with the username or the password you should redirect the user to “index.php”. Use **PHP_SELF** in this form.
